BIRMINGHAM

Category Theory

Midlands Graduate School 2026

Sergey Goncharov

April 13–17, 2026

Big Picture / Motivation

- **Category theory** is a “theory”, like **set theory**, like **group theory**, like **type theory**
- Types in functional programming $\leadsto$ sets (or set-like objects)
- Functions $\leadsto$ arrows/morphisms between types
- Category theory gives language to talk about **how** we compose computations, abstract patterns, and universal constructions that mirror programming constructs (pairs, function types, currying)
- It provides means of **abstraction** to reason and prove things **generically**, instead of on case-by-case basis

Course Outline

Part I: Sets and Warm-Up

Sets, functions, isomorphisms,
quotients and equivalences

Part II: Categories & Functors

Definitions and examples, products,
coproducts, commutative diagrams,
universal properties

Part III: Natural Transformations

Natural transformations, exponentials,
Yoneda Theorem

Part IV: Adjunctions & Free Objects

Adjunctions, free objects,
initial algebras, induction

Sets and Warm-Up

Why Begin with Sets?

- Mathematics builds on sets
- Types in programming follow set intuition
- Category theory (standardly) also builds on sets
- But: what exactly is a set?
 - OK, that is too ambitious – what is it roughly?
- We start with sets to discover something deeper is hiding underneath

Naïve (Philosophical) Sets

- Set is collection of objects, like

$$X = \left\{ \text{⚽}, \text{🐕}, \pi, \mathbb{N}, \text{♥} \right\}$$

- We write $x \in X$ to say that x is **member** of X , e.g. $\pi \in X$
- **Empty set** $\emptyset = \{ \}$ is a set of no elements
- There are various mechanisms to construct larger sets
- **Set comprehension**

$$\{x \in S \mid P(x)\} \quad \text{e.g.} \quad \text{evens} = \{n \in \mathbb{N} \mid \exists m \in \mathbb{N}. n = 2m\}$$

Intuition: Sets are containers

Finite Sets v.s. Finite Lists

- **(Finite) lists** over set X : $\text{List}(X) = \{[x_1, \dots, x_n] \mid n \in \mathbb{N}, x_1 \in X, \dots, x_n \in X\}$
- **Notation:** $[]$ – **empty list**, $x :: xs$ – list with **head** x and **tail** xs . E.g. $x :: [] = [x]$
- Finite sets are lists, where we additionally enable
 - **Commutativity:** $[\dots, x, y, \dots] \equiv [\dots, y, x, \dots]$
 - **Idempotence:** $[\dots, x, x, \dots] \equiv [\dots, x, \dots]$
- **(Finite) Multisets** = lists with commutativity, but not idempotence. Thus

Lists < Multisets < Sets

Sets (Slightly More) Formally

- Set theory postulates: everything is a set
- Only primitive relation between sets is ' $\in$ '

We then derive:

- **Natural numbers:** $0 = \emptyset$, $1 = \{0, \emptyset\} = \{\emptyset\}$, $2 = \{1, \emptyset\} = \{\{\emptyset\}, \emptyset\}, \dots$
- Set inclusion: $X \subseteq Y$ if $\forall x \in X. x \in Y$
 - **Extensionality axiom:** $X = Y$ if and only if $X \subseteq Y$ and $Y \subseteq X$
- **Powerset:** $Y \in \mathcal{P}(X)$ if and only if $Y \subseteq X$
- **Relations:** $R \subseteq X \times Y$
- **Functions:** $f: X \rightarrow Y$ – such relations $R \subseteq X \times Y$ that for every $x \in X$ there is unique $y \in Y$ with $x R y$
 - So, in set theory: Sets $\leadsto$ Relations $\leadsto$ Functions

Empty Set and Singleton Sets

- No controversy about empty set: $\emptyset = \{ \}$ – set with no elements
- But what is one-element set? $\{\oplus\}$? $\{\text{🐕}\}$? $\{\pi\}$?
- $\{\emptyset\}$ is good candidate
- For every set S , $\{S\}$ is also singleton set
- Singleton sets are characterized by property: they are sets with exactly one element
- $\{\emptyset\}$ is a concrete **representative** in the **class** of all singletons

Note on Classes

- All sets do not form a set, but a **class**

$\text{Set} < \text{Class}$

- Division into sets and proper classes is way to avoid paradoxes
- Other approach: **universes**

$\text{Set}_0 < \text{Set}_1 < \text{Set}_2 < \dots$

where the union of all sets in Set_i is in Set_{i+1}

- By saying “set” we can imagine set from Set_i , and by saying “class” we can imagine set from Set_{i+1}

Natural Numbers as Sets

- In computer science, we count from 0: $\mathbb{N} = \{0, 1, \dots\}$!
- **Von Neumann numerals:** $0 := \emptyset, n + 1 := n \cup \{n\}$ So:

$$0 = \emptyset, \quad 1 = \{\emptyset\}, \quad 2 = \{\emptyset, \{\emptyset\}\}, \quad 3 = \{\emptyset, \{\emptyset\}, \{\emptyset, \{\emptyset\}\}\}, \dots$$

This is very convenient, because $n + 1 = \{0, \dots, n\}$

- Alternatively **Zermelo numerals:** $0 := \emptyset, n + 1 := \{n\}$. This is less convenient

Ordered Pairs and Products

We would like to define **Cartesian products** $X \times Y = \{(x, y) \mid x \in X, y \in Y\}$. But what is (x, y) ?

- **Kuratowski definition:** $(x, y) := \{\{x\}, \{x, y\}\}$
- Then (**PROVE IT**):

$$(x, y) = (x', y') \iff x = x' \text{ and } y = y'.$$

- Using this, we can define:

$$X \times Y := \left\{ \{\{x\}, \{x, y\}\} \subseteq \mathcal{P}(X \cup Y) \mid x \in X, y \in Y \right\}$$

Pairs and Cartesian products are **constructed objects**!

Disjoint Unions

- **Union of sets:** $x \in X \cup Y$ iff $x \in X$ or $x \in Y$
- How to define **Disjoint Union** $X + Y (= X \uplus Y)$?
- Maybe $X + Y = \{(x, \text{🔑}) \mid x \in X\} \cup \{(x, \text{🔧}) \mid y \in Y\}$?

Disjoint Unions

- **Union of sets:** $x \in X \cup Y$ iff $x \in X$ or $x \in Y$
- How to define **Disjoint Union** $X + Y (= X \uplus Y)$?
- Maybe $X + Y = \{(x, \text{🔑}) \mid x \in X\} \cup \{(x, \text{🔧}) \mid y \in Y\}$?
- Maybe $X + Y = \{(x, \text{🍔}) \mid x \in X\} \cup \{(x, \text{🐘}) \mid y \in Y\}$?

Disjoint Unions

- **Union of sets:** $x \in X \cup Y$ iff $x \in X$ or $x \in Y$
- How to define **Disjoint Union** $X + Y (= X \uplus Y)$?
- Maybe $X + Y = \{(x, \text{🔑}) \mid x \in X\} \cup \{(x, \text{🔧}) \mid y \in Y\}$?
- Maybe $X + Y = \{(x, \text{🍔}) \mid x \in X\} \cup \{(x, \text{🐘}) \mid y \in Y\}$?
- More seriously: $X + Y = \{(x, 0) \mid x \in X\} \cup \{(x, 1) \mid y \in Y\}$

Now compute with von Neumann numerals: $1 = \{0\}$, $2 = \{0, 1\}$. Then

$$1 + 1 = \{(1, 0), (1, 1)\} = \{\{ \{1\}, \{1, 0\} \}, \{ \{1\} \} \}$$

This is **not** equal to $2 = \{0, 1\}$! So

$$1 + 1 \neq 2$$

Functions between Sets

- Function $f: X \rightarrow Y$, assigns each $x \in X$ a unique $f(x) \in Y$
- Functions $f: X \rightarrow Y$ are special relations $f \subseteq X \times Y$
- Identity function $\text{id}_X: X \rightarrow X$, $\text{id}_X(x) = x$
- Equality of functions $f = g$ if for all x , $f(x) = g(x)$
 - This is provable principle (**PROVE IT**), called **function extensionality**

Composition:

$$(g \circ f)(x) = g(f(x))$$

Proposition: $f \circ \text{id} = f$, $\text{id} \circ f = f$ and $f \circ (g \circ h) = (f \circ g) \circ h$ (associativity)

Bijection vs Isomorphism

Function $f: X \rightarrow Y$ is

- **Injection** if $f(x) = f(x')$ entails $x = x'$
- **Surjection** if for every $y \in Y$ there is $x \in X$, such that $f(x) = y$
- **Bijection** if it is both injection and surjection

Alternative view: $f: X \rightarrow Y$ is **isomorphism** if for some $f^{-1}: Y \rightarrow X$,

$$f \circ f^{-1} = \text{id}_Y \quad \text{and} \quad f^{-1} \circ f = \text{id}_X$$

Proposition: f is bijection if and only if f is isomorphism

Some Properties of Isomorphisms

It follows that (**PROVE IT**)

- f^{-1} is unique if exists
- If f is isomorphism, so is f^{-1}
- id is isomorphism and $\text{id}^{-1} = \text{id}$
- Composition of isomorphisms $f \circ g$ is isomorphism and $(f \circ g)^{-1} = g^{-1} \circ f^{-1}$

These are derivable from definition, without using that isomorphism = bijection!

Notation: $X \cong Y$ if there is isomorphism $f: X \rightarrow Y$

Up-to Isomorphism

- Big innovation of category theory: work with things via their descriptions
- We narrow down objects of interest as those that “fit best” to such description
- Such descriptions together with their best-fit condition are called **universal properties**
- They determine objects not uniquely, but **up-to isomorphism**

Example. A **singleton set** 1 is characterised by: there is exactly one function $X \rightarrow 1$ for every set X

- $\{\emptyset\}$, $\{\{\emptyset\}\}$, $\{\odot\}$ all satisfy this — and are all isomorphic
- Any two singletons are isomorphic, so we speak of **the singleton up to isomorphism**

Induction/Recursion for Natural Numbers

- Set theory postulates existence of natural numbers $\mathbb{N}$ as smallest set that contains $0 = \emptyset$ and closed under $n \mapsto n + 1 := n \cup \{n\}$
- Induction** is paraphrasing this: if $P \subseteq \mathbb{N}$ with $0 \in P$ and $n \in P \Rightarrow n+1 \in P$, then $P = \mathbb{N}$
 - Because predicates over $\mathbb{N} \iff$ subsets of $\mathbb{N}$:

$$P(0) \wedge (\forall n. P(n) \Rightarrow P(n+1)) \Rightarrow \forall n. P(n)$$

- (Structural) Recursion**: for any $a \in A$ and $h: A \rightarrow A$, there is unique $f: \mathbb{N} \rightarrow A$ with

$$f(0) = a \qquad f(n+1) = h(f(n))$$

- Primitive recursion** is derivable from recursion (**PROVE IT**): for any $g: X \rightarrow A$ and $h: A \times X \times \mathbb{N} \rightarrow A$, there is unique $f: X \times \mathbb{N} \rightarrow A$ with

$$f(x, 0) = g(x) \qquad f(x, n+1) = h(f(x, n), x, n)$$

Induction/Recursion for Lists

- Given set X , $\text{List}(X)$ is constructable as smallest set that contains $[]$ and closed under $xs \mapsto x :: xs$ for $x \in X$
- **Induction:** $P([]) \wedge (\forall x \in X, xs. P(xs) \Rightarrow P(x :: xs)) \Rightarrow \forall xs. P(xs)$
- **(Structural) Recursion:** for any $a \in A$ and $h: X \times A \rightarrow A$, there is unique $f: \text{List}(X) \rightarrow A$ with

$$f([]) = a \qquad f(x :: xs) = h(x, f(xs))$$

Questions:

- What is primitive recursion for lists?
- Why it is derivable (**PROVE IT**)
- Define length and concatenation recursively

Remarks:

- Structural recursion $\neq$ general recursion (no arbitrary self-calls)
- Induction — proof principle; recursion — definition principle

Categories & Functors

Definition of Category

Category $\mathcal{C}$ consists of:

- Class of objects $\text{Ob}(\mathcal{C})$
- For every A, B set of morphisms $\text{Hom}_{\mathcal{C}}(A, B)$. Write $f: A \rightarrow B$
- Composition: if $f: A \rightarrow B$ and $g: B \rightarrow C$ then $g \circ f: A \rightarrow C$
- Identity morphisms $\text{id}_A: A \rightarrow A$

Subject to **associativity** $(h \circ g) \circ f = h \circ (g \circ f)$ and **identity laws** $\text{id} \circ f = f = f \circ \text{id}$

We can imagine categories as (multi)graphs: objects = nodes, morphisms = edges

Sets as Category

Category of sets **Set**

- **Objects:** sets
- **Morphisms:** functions between sets
- Composition: usual function composition
- Identities: identity functions

Further set-like categories (objects = sets, identities = identity functions):

- Relations (**Rel**) – morphisms are relations
- Partial functions
- Injections
- Isomorphisms
- ...

Category Pos

- **Objects:** partially ordered sets $(P, \leq)$
- **Morphisms:** monotone functions

$$f: (P, \leq_P) \rightarrow (Q, \leq_Q)$$

such that

$$x \leq_P y \Rightarrow f(x) \leq_Q f(y)$$

Example:

Category Mon

- **Objects:** monoids $(M, \cdot, e)$
- **Morphisms:** **monoid homomorphisms** are maps $f: M \rightarrow N$, such that unit and multiplication are preserved:

$$f(x \cdot y) = f(x) \cdot f(y) \qquad f(e_M) = e_N$$

Example: $\text{length}: (\text{List}(A), ++, []) \rightarrow (\mathbb{N}, +, 0)$ — preserves unit and multiplication:

$$\text{length}([]) = 0$$

$$\text{length}(xs ++ ys) = \text{length}(xs) + \text{length}(ys)$$

Monoid as One-Object Category

Fix some monoid $(M, \cdot, e)$. We can turn it into category!

- **Objects:** — exactly one, say $\bullet$
- **Morphisms:** $\text{Hom}(\bullet, \bullet) = M$
- Composition is given by monoid multiplication
- Identity given by e

This is equivalence: Monoids $\iff$ one-object categories (**PROVE IT**)

Monoid homomorphisms $\iff$ functors between one-object categories (**PROVE IT**)

Posets as Categories

Fix poset $(P, \leq)$. It is also category:

- **Objects:** elements of P
- **Morphisms:** $\text{Hom}(x, y) = \{\star\}$ if $x \leq y$ and $\text{Hom}(x, y) = \emptyset$ otherwise
(at most one morphism between two objects)
- Unit of composition = reflexivity
- Associativity of composition = transitivity

Hint: Categorical notions become **order-theoretic** when instantiated to poset-categories.
To understand a complex categorical notion, instantiate it to poset-category!

Example Categories: Summary

Category	Objects	Morphisms	Composition
Set	sets	functions	function composition
Pos	posets	monotone maps	function composition
Mon	monoids	homomorphisms	function composition
Rel	sets	relations $R \subseteq X \times Y$	relational composition
$(P, \leq)$	elements of P	$\star$ if $x \leq y$	transitivity
$(M, \cdot, e)$	$\{\star\}$	elements of M	monoid multiplication

Commutative Diagrams

- For $f: A \rightarrow B$, we can express $f \circ \text{id}_A = f$ and $\text{id}_B \circ f = f$ diagrammatically:

- Associativity:

But that is redundant, because we read sequence f, g as $g \circ f$ – associativity is baked in!

Isomorphisms

Morphism $f: A \rightarrow B$ is an **isomorphism** if there exists $f^{-1}: B \rightarrow A$ with $f^{-1} \circ f = \text{id}_A$ and $f \circ f^{-1} = \text{id}_B$:

- A and B are **isomorphic**, written $A \cong B$, if such f exists
- f^{-1} is unique: if $g \circ f = \text{id}_A$ and $f \circ g = \text{id}_B$, then

$$g = g \circ \text{id}_B = g \circ (f \circ f^{-1}) = (g \circ f) \circ f^{-1} = \text{id}_A \circ f^{-1} = f^{-1}$$

- In **Set**: isomorphism = bijection; in **Pos**: order-isomorphism; in **Mon**: monoid isomorphism
- **Group** is one-object category in which every morphism is isomorphism (**PROVE IT**)

Commutative Diagrams and Equational Reasoning

A diagram **commutes** if every directed path with the same start and end gives the same composite.

If all three squares commute:

$$b \circ f = h \circ a, \quad c \circ g = k \circ b, \quad q \circ k = r \circ p$$

then the outer paths from A to H agree:

$$\begin{aligned} q \circ c \circ g \circ f &= q \circ (k \circ b) \circ f \\ &= (q \circ k) \circ (b \circ f) \\ &= (r \circ p) \circ (h \circ a) \\ &= r \circ p \circ h \circ a \end{aligned}$$

Thus, commutative diagrams = pictorial representations of equational proofs!

Not Every Diagram Proves Something

Commuting cells (by assumption):

$$h \circ f \circ u = k$$

$$p \circ g \circ u = j$$

$$r \circ k = q \circ j$$

Chaining all three:

$$(r \circ h \circ f) \circ u = r \circ k$$

$$= q \circ j$$

$$= (q \circ p \circ g) \circ u$$

But this does not imply $r \circ h \circ f = q \circ p \circ g$, because we generally cannot discard u !

Terminal and Initial Objects

In category $\mathcal{C}$:

- **Terminal object** 1: for every object A there is exactly one morphism $A \rightarrow 1$
- **Initial object** 0: for every object A there is exactly one morphism $0 \rightarrow A$

Examples:

- In **Set**: any singleton $\{*\}$ is terminal; $\emptyset$ is initial
- In **Pos**: any one-element poset is terminal; $\emptyset$ is initial
- In **Mon**: trivial monoid $\{e\}$ is terminal and initial
- In every poset category: terminal = **greatest element**; initial = **least element**

Key viewpoint: elements of X in **Set** correspond to arrows $1 \rightarrow X$, i.e.

$\text{elements}(X) \cong \text{Hom}(1, X)$. So, $f(x)$ must be interpreted as composition $1 \xrightarrow{x} X \xrightarrow{f} Y$!

Product Universal Property

- **Object:** a product of X and Y is an object Z
- **Diagram (span):** morphisms $p_1: Z \rightarrow X$ and $p_2: Z \rightarrow Y$
- **Universal property:** for any $f: A \rightarrow X$ and $g: A \rightarrow Y$ there is a **unique** $h: A \rightarrow Z$ with $p_1 \circ h = f$ and $p_2 \circ h = g$:

Selected product $X \times Y$: specific **choice** of product for every pair (X, Y) ; all products of X and Y are **uniquely isomorphic**

Notation: With $X \times Y$, use fst , snd for the chosen projections; $\langle f, g \rangle$ for the induced h

Examples of Products

- **Set:** $X \times Y = \{(x, y) \mid x \in X, y \in Y\}$; projections $(x, y) \mapsto x$ and $(x, y) \mapsto y$; pairing $\langle f, g \rangle(x) = (f(x), g(x))$
- **Pos:** $X \times Y$ with pointwise order: $(x, y) \leq (x', y')$ iff $x \leq x'$ and $y \leq y'$
- **Mon:** componentwise monoid $(M \times N, \cdot, (e_M, e_N))$ where

$$(m, n) \cdot (m', n') = (m \cdot m', n \cdot n')$$

- **Poset category:** product of x and y = **meet** $x \wedge y$ (=greatest lower bound), when it exists

Products are Up-To-Isomorphism

Let (Z, p_1, p_2) and (Z', p'_1, p'_2) both be products of X and Y :

- Universal property of Z : $\exists! i: Z' \rightarrow Z$ with $p_1 \circ i = p'_1$, $p_2 \circ i = p'_2$
- Universal property of Z' on $\text{span}(p_1, p_2)$: $\exists! j: Z \rightarrow Z'$ with $p'_1 \circ j = p_1$, $p'_2 \circ j = p_2$
- By uniqueness: $j \circ i = \text{id}_{Z'}$
- By symmetric argument: $i \circ j = \text{id}_Z$, so $Z \cong Z'$

Example: Take selected product $(X \times Y, \text{fst}, \text{snd})$. Then $(Y \times X, \text{snd}, \text{fst})$ is also product of X and Y – isomorphism $\text{swap} = \langle \text{snd}, \text{fst} \rangle: X \times Y \xrightarrow{\sim} Y \times X$

Axioms of Binary Products

For selected products, one can show (**PROVE IT**) :

$$(\beta_1) \text{fst} \circ \langle f, g \rangle = f$$

$$(\beta_2) \text{snd} \circ \langle f, g \rangle = g$$

$$(\eta) \langle \text{fst}, \text{snd} \rangle = \text{id}_{X \times Y}$$

$$(\text{nat}) \langle f, g \rangle \circ h = \langle f \circ h, g \circ h \rangle$$

Theorem: This is a **sound** and **complete** axiomatization of binary products (**PROVE IT**)

Example (uniqueness of pairing): if $\text{fst} \circ k = f$ and $\text{snd} \circ k = g$, then

$$k = \text{id} \circ k \stackrel{(\eta)}{=} \langle \text{fst}, \text{snd} \rangle \circ k \stackrel{(\text{nat})}{=} \langle \text{fst} \circ k, \text{snd} \circ k \rangle \stackrel{(\text{assm.})}{=} \langle f, g \rangle$$

Dual Category

Given category $\mathcal{C}$, the **opposite category** $\mathcal{C}^{\text{op}}$ has:

- Same objects as $\mathcal{C}$
- Morphisms reversed: $f: A \rightarrow B$ in $\mathcal{C}$ becomes $f^{\text{op}}: B \rightarrow A$ in $\mathcal{C}^{\text{op}}$
- Composition: $g^{\text{op}} \circ f^{\text{op}} = (f \circ g)^{\text{op}}$

Principle of Duality: any theorem proved in $\mathcal{C}$ yields a dual theorem in $\mathcal{C}^{\text{op}}$ — just reverse all arrows

Examples:

- Poset $(P, \leq)^{\text{op}} = \text{poset with reversed order } (P, \geq)$
- Initial objects in $\mathcal{C}$ = terminal objects in $\mathcal{C}^{\text{op}}$

Coproduct via Duality

Coproduct = product in $\mathcal{C}^{\text{op}}$ — obtained by reversing all arrows in the product definition

- **Object:** a coproduct of X and Y is an object Z
- **Diagram (cospan):** morphisms $\iota_1: X \rightarrow Z$ and $\iota_2: Y \rightarrow Z$
- **Universal property:** for any $f: X \rightarrow A$ and $g: Y \rightarrow A$ there is a **unique** $h: Z \rightarrow A$ with $h \circ \iota_1 = f$ and $h \circ \iota_2 = g$:

Selected coproduct $X + Y$: choice of coproduct for every pair; notation inl, inr for chosen injections; $[f, g]$ — **co-pairing** — for the induced h

Example: In **Set**, $X + Y = \text{disjoint union}$ (**PROVE IT**)

Axioms of Binary Coproducts

For selected coproducts, one can show:

$$(\beta_1) [f, g] \circ \text{inl} = f$$

$$(\beta_2) [f, g] \circ \text{inr} = g$$

$$(\eta) [\text{inl}, \text{inr}] = \text{id}_{X+Y}$$

$$(\text{nat}) h \circ [f, g] = [h \circ f, h \circ g]$$

Theorem: This is **sound** and **complete** axiomatization of binary coproducts

Proof: Duality

Example: Every $f: X + Y \rightarrow Z$ has form $[f_1, f_2]$ for $f_1: X \rightarrow Z, f_2: Y \rightarrow Z$. Indeed:

$$f = f \circ \text{id} \stackrel{(\eta)}{=} f \circ [\text{inl}, \text{inr}] \stackrel{(\text{nat})}{=} [f \circ \text{inl}, f \circ \text{inr}]$$

Categories & Functors

Functors

Definition of Functor

- **(Covariant) Functor** $F: \mathcal{C} \rightarrow \mathcal{D}$ assigns:
 - To every object $A \in \text{Ob}(\mathcal{C})$ an object $F(A) \in \text{Ob}(\mathcal{D})$
 - To every morphism $f: A \rightarrow B$ a morphism $F(f): F(A) \rightarrow F(B)$

preserving composition and identities:

$$F(g \circ f) = F(g) \circ F(f) \quad F(\text{id}_A) = \text{id}_{F(A)}$$

- Functor $F: \mathcal{C} \rightarrow \mathcal{C}$ is called **endofunctor**
- Functors compose: $(GF)(A) = G(F(A))$, $(GF)(f) = G(F(f))$; categories and functors form the category **Cat** — **category of categories** modulo size issues (sets vs. classes)

Examples of Functors

Endofunctors on Set:

- Powerset: $\mathcal{P}(X)$; on $f: X \rightarrow Y$ acts as direct image $\mathcal{P}(f) = f[-]$
- List: $\text{List}(X)$ = finite lists over X ; $\text{List}(f)([x_1, \dots, x_n]) = [f(x_1), \dots, f(x_n)]$
- Maybe: $X \mapsto X + \{\text{Nothing}\}$; $\text{Maybe}(f)(\text{inl } x) = \text{inl } f(x)$, $\text{Maybe}(f)(\text{inr } x) = \text{inr } x$

Between different categories:

- **Forgetful functor** $U: \mathbf{Mon} \rightarrow \mathbf{Set}$: sends $(M, \cdot, e)$ to M , homomorphisms to functions
- **Free monoid functor** $F: \mathbf{Set} \rightarrow \mathbf{Mon}$: sends X to $\text{List}(X)$

Product Category and Bifunctors

Product category $\mathcal{C} \times \mathcal{D}$: objects are pairs (A, B) ; morphisms $(A, B) \rightarrow (A', B')$ are pairs (f, g) of morphisms $f: A \rightarrow A', g: B \rightarrow B'$; composition componentwise

Bifunctor $F: \mathcal{C} \times \mathcal{D} \rightarrow \mathcal{E}$: functor on product category. Unraveling definition:

- $F(\text{id}_A, \text{id}_B) = \text{id}_{F(A, B)}$
- $F(f' \circ f, g' \circ g) = F(f', g') \circ F(f, g)$

Example: binary product $(- \times -): \mathcal{C} \times \mathcal{C} \rightarrow \mathcal{C}$ (if $\mathcal{C}$ has binary products): on morphisms $f: A \rightarrow A', g: B \rightarrow B'$, gives

$$f \times g = \langle f \circ \text{fst}, g \circ \text{snd} \rangle: A \times B \rightarrow A' \times B'$$

Contravariant and Mixed-Variance Functors

Contravariant functor $F: \mathcal{C}^{\text{op}} \rightarrow \mathcal{D}$: sends $f: A \rightarrow B$ to $F(f): F(B) \rightarrow F(A)$; reverses composition: $F(g \circ f) = F(f) \circ F(g)$

Mixed variance $F: \mathcal{C}^{\text{op}} \times \mathcal{D} \rightarrow \mathcal{E}$: **contravariant** in first argument, **covariant** in second

Example: $\text{Hom}(-, -): \mathcal{C}^{\text{op}} \times \mathcal{C} \rightarrow \mathbf{Set}$ is mixed-variance (see next slide)

Duality: contravariant functor $\mathcal{C}^{\text{op}} \rightarrow \mathcal{D}$ is the same as covariant functor $\mathcal{C} \rightarrow \mathcal{D}^{\text{op}}$; choice of perspective is a matter of convention

Functors: Further Examples

Hom-functor $\text{Hom}(-, -): \mathcal{C}^{\text{op}} \times \mathcal{C} \rightarrow \mathbf{Set}$:

- $\text{Hom}(A, -): \mathcal{C} \rightarrow \mathbf{Set}$ — covariant; acts by **post**composition: $h \mapsto f \circ h$
- $\text{Hom}(-, B): \mathcal{C}^{\text{op}} \rightarrow \mathbf{Set}$ — contravariant; acts by **pre**composition: $h \mapsto h \circ f$
- For $f: A' \rightarrow A$ and $g: B \rightarrow B'$, $\text{Hom}(f, g)$ sandwiches input between f and g :

$$\text{Hom}(f, g): \text{Hom}(A, B) \rightarrow \text{Hom}(A', B'), \quad h \mapsto g \circ h \circ f$$

Contravariant powerset sends $X \mapsto \mathcal{P}(X)$ and $f: X \rightarrow Y$ to $f^{-1}[-]: \mathcal{P}(Y) \rightarrow \mathcal{P}(X)$

This is the same as $\text{Hom}_{\mathbf{Set}}(X, 2)$ (**PROVE IT**)

Full and Faithful Functors

Functor $F: \mathcal{C} \rightarrow \mathcal{D}$ induces maps on hom-sets:

$$F_{A,B}: \text{Hom}_{\mathcal{C}}(A, B) \rightarrow \text{Hom}_{\mathcal{D}}(FA, FB), \quad f \mapsto F(f)$$

- F is **faithful** if every $F_{A,B}$ is injective
- F is **full** if every $F_{A,B}$ is surjective
- F is **fully faithful** if every $F_{A,B}$ is a bijection

Examples:

- Forgetful $U: \mathbf{Mon} \rightarrow \mathbf{Set}$: **faithful** (distinct hom's remain distinct) but not full (not every function is a homomorphism)
- Inclusion $(P, \leq) \hookrightarrow \mathbf{Set}$ via poset-as-category: **faithful** (Hom has at most one element), not full in general

To Be Continued ...
